Stationary and Randomized Heston model

The model

Dynamic of the asset price process $(S_t)_{t\geqslant 0}$ and its volatility $(v_t)_{t\geqslant 0}$ is given by

$$\begin{cases} dS_t = S_t \left(rdt + \sqrt{v_t} dW_t \right) \\ dv_t = \kappa(\theta - v_t) dt + \xi \sqrt{v_t} d\widetilde{W}_t \end{cases}$$

- $S_0 = s_0$ is the initial value of the process,
- \bullet κ the mean reverting term,
- \bullet the long run average price variance,
- ξ is the volatility of the volatility,
- (W,\widetilde{W}) is a standard correlated 2d Brownian motion with correlation ρ ,

Stationary and Randomized Heston model

The model

T. Montes Optimal Quantization 7 / 31

Definitions

Let $\Gamma_N = \{x_1^N, \dots, x_N^N\} \subset \mathbb{R}$, a subset of size N, called N-quantizer, we define:

• The *Voronoï partition* of $\mathbb R$ induced by the *N*-quantizer:

$$C_i(\Gamma_N) = (x_{i-1/2}^N, x_{i+1/2}^N], \quad i \in [\![1,N-1]\!], \quad C_N(\Gamma_N) = (x_{N-1/2}, x_{N+1/2}^N).$$

Easily defined in dimension one.

• The Voronoï Quantization of the random variable X:

$$\widehat{X}^{\Gamma_N} = \operatorname{Proj}_{\Gamma_N}(X) = \sum_{i=1}^N x_i^N \, \mathbb{1}_{X \in C_i(\Gamma_N)}$$

T. Montes

Definitions

Let $\Gamma_N = \{x_1^N, \dots, x_N^N\} \subset \mathbb{R}$, a subset of size N, called N-quantizer, we define:

• The *Voronoï partition* of $\mathbb R$ induced by the *N*-quantizer:

$$C_i(\Gamma_N) = (x_{i-1/2}^N, x_{i+1/2}^N], \quad i \in [\![1,N-1]\!], \quad C_N(\Gamma_N) = (x_{N-1/2}, x_{N+1/2}^N).$$

Easily defined in dimension one.

• The *Voronoi Quantization* of the random variable X:

$$\widehat{X}^{\Gamma_N} = \operatorname{Proj}_{\Gamma_N}(X) = \sum_{i=1}^N x_i^N \, \mathbb{1}_{X \in C_i(\Gamma_N)}$$

• It is convenient to define the quadratic distortion function at level N:

$$\mathcal{Q}_{2,N}: x = (x_1^N, \dots, x_N^N) \longmapsto \mathbb{E}\left[\min_{i \in [1,N]} |X - x_i^N|^2\right] = \|X - \widehat{X}^N\|_2^2.$$

T. Montes Optimal Quantization

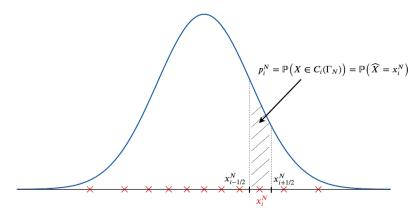

Figure: Gaussian Optimal Quantization

T. Montes Optimal Quantization 9 / 31

How to build an Optimal Quantizer?

1. Differentiate the $Q_{2,N}$

The gradient is given by

$$\nabla \mathcal{Q}_{2,N}(x_{_{\mathbf{1}:N}}) = \left(\mathbb{E}\left[\left(x_{i}^{N} - X\right)\mathbb{1}_{X \in (x_{i-1/2}^{N}, x_{i+1/2}^{N}]}\right]\right)_{i=1,\dots,N}$$

2. Solve the fixed point problem

Then, find $x_{1:N}$ that cancel the gradient

$$\begin{split} \nabla \mathcal{Q}_{2,\mathsf{N}}\left(x_{_{\mathbf{1}:\mathsf{N}}}\right) &= 0 &\iff & x_{_{i}}^{N} = \frac{\mathbb{E}\left[X \, \mathbb{1}_{X \in (x_{_{i-1/2}}^{N}, x_{_{i+1/2}}^{N}]}\right]}{\mathbb{P}\left(X \in (x_{_{i-1/2}}^{N}, x_{_{i+1/2}}^{N}]\right)}, \qquad i = 1, \dots, N \\ &\iff & x_{_{i}}^{N} = \frac{K_{_{x}}(x_{_{i+1/2}}^{N}) - K_{_{x}}(x_{_{i-1/2}}^{N})}{F_{_{x}}(x_{_{i+1/2}}^{N}) - F_{_{x}}(x_{_{i-1/2}}^{N})}, \qquad i = 1, \dots, N \end{split}$$

The price of the European option on the asset $S_T^{v_0}$ is given by

$$I_0 := \mathbb{E}\left[e^{-rT}\varphi(S_T^{v_0})\right].$$

By preconditioning we have

$$I_0 = \mathbb{E}\left[\mathbb{E}\left[e^{-rT}\varphi(S_T^{v_0}) \mid \sigma(v_0)\right]\right] = \mathbb{E}\left[f(v_0)\right]$$

where f(v) is the price of the European option in the Standard Heston model with deterministic initial conditions for a given initial volatility v.

The price of the European option on the asset $S_T^{v_0}$ is given by

$$I_0 := \mathbb{E}\left[e^{-rT}\varphi(S_T^{v_0})\right].$$

By preconditioning we have

$$I_0 = \mathbb{E}\left[\mathbb{E}\left[e^{-rT}\varphi(S_T^{v_0}) \mid \sigma(v_0)\right]\right] = \mathbb{E}\left[f(v_0)\right]$$

where f(v) is the price of the European option in the Standard Heston model with deterministic initial conditions for a given initial volatility v.

Cubature formula

- Build an optimal quantizer of $v_0 \sim \Gamma(\alpha, \beta)$
- Approximate I_0 using the following quantization-based cubature formula

$$\widehat{I}_0^N := \mathbb{E}\left[f(\widehat{v}_0^N)\right] = \sum_{i=1}^N f(v_{0,i}^N) \, \mathbb{P}(\widehat{v}_0^N = v_{0,i}^N).$$

• Fast convergence of \hat{l}_0^N toward l_0 , for smooth enough functions f

$$\lim_{N \to +\infty} N^2 \big| \mathbb{E} \big[f(v_0) \big] - \mathbb{E} \big[f(\widehat{v}_0^N) \big] \big| < C_{v_0,f} < +\infty.$$

T. Montes

• Fast convergence of \widehat{I}_0^N toward I_0 , for smooth enough functions f

$$\lim_{N \to +\infty} N^2 \big| \mathbb{E} \left[f(v_0) \right] - \mathbb{E} \left[f(\widehat{v}_0^N) \right] \big| < C_{v_0,f} < +\infty.$$

• From European options (preconditioning by v_0 at time t_0) to path-dependent ones (need to precondition by $(v_k)_{k=0:n}$ at time t_k 's).

Model transformation

$$\begin{cases} dS_t = S_t \left(r dt + \sqrt{v_t} dW_t \right) \\ dv_t = \kappa (\theta - v_t) dt + \xi \sqrt{v_t} d\widetilde{W}_t \end{cases}$$

Remark

 v_t is autonomous, hence 1d problem (again).

Model transformation

$$\begin{cases} dS_t = S_t \left(rdt + \sqrt{v_t} dW_t \right) \\ dv_t = \kappa(\theta - v_t) dt + \xi \sqrt{v_t} d\widetilde{W}_t \end{cases}$$

Remark

 v_t is autonomous, hence 1d problem (again).

We will be working with (X_t, Y_t) that are transformation of (S_t, v_t) :

- For the volatility $\longrightarrow Y_t = e^{\kappa t} v_t$
- For the asset $\longrightarrow X_t = \log(S_t)$

First, the volatility

Milstein Scheme (preserving the positivity)

We consider the following boosted volatility process: let $Y_t = e^{\kappa t} v_t, t \in [0, T]$.

$$dY_t = e^{\kappa t} \kappa \theta dt + \xi e^{\frac{\kappa t}{2}} \sqrt{Y_t} d\widetilde{W}_t.$$

Now, if we look at the Milstein discretization scheme of Y_t

$$\overline{Y}_{t_{k+1}} = \mathcal{M}^{\Delta}_{\widetilde{b},\widetilde{\sigma}}(t_k,\overline{Y}_{t_k},\widetilde{Z}_{k+1})$$

where $\widetilde{Z}_{k+1} \sim \mathcal{N}(0,1)$ and

$$\mathcal{M}_{\tilde{b},\tilde{\sigma}}^{\Delta}(t,x,z) := x - \frac{\tilde{\sigma}(t,x)}{2\tilde{\sigma}_{x}'(t,x)} + \Delta\left(\tilde{b}(t,x) - \frac{\tilde{\sigma}\tilde{\sigma}_{x}'(t,x)}{2}\right) + \frac{\tilde{\sigma}\tilde{\sigma}_{x}'(t,x)\Delta}{2}\left(z + \frac{1}{\sqrt{\Delta}\tilde{\sigma}_{x}'(t,x)}\right)^{2}$$

with

$$\widetilde{b}(t,x) := \mathrm{e}^{\kappa t} \, \kappa \theta, \qquad \widetilde{\sigma}(t,x) := \xi \sqrt{x} \, \mathrm{e}^{\frac{\kappa t}{2}} \quad \text{ and } \quad \widetilde{\sigma}_x'(t,x) := \frac{\xi \, \mathrm{e}^{\frac{\kappa t}{2}}}{2\sqrt{x}}.$$

Then, the log-asset

Euler-Maruyama scheme

We consider the logarithm of the asset $X_t := \log(S_t)$, yielding

$$dX_t = \left(r - \frac{v_t}{2}\right)dt + \sqrt{v_t}dW_t.$$

Now, using an Euler-Maruyama scheme for the discretization of X_t , we have

$$\begin{cases} \bar{X}_{t_{k+1}} = \mathcal{E}^{\Delta}_{b,\sigma}(t_k, \bar{X}_{t_k}, \bar{Y}_{t_k}, Z_{k+1}) \\ \bar{Y}_{t_{k+1}} = \mathcal{M}^{\Delta}_{\tilde{b},\tilde{\sigma}}(t_k, \bar{Y}_{t_k}, \tilde{Z}_{k+1}) \end{cases}$$

where $Z_{k+1} \sim \mathcal{N}(0,1)$ and $\operatorname{Corr}(Z_{k+1},\widetilde{Z}_{k+1}) = \rho$ and

$$\mathcal{E}_{b,\sigma}^{\Delta}(t,x,y,z) := x + b(t,x,y)\Delta + z\sigma(t,x,y)\sqrt{\Delta}$$

with

$$b(t, x, y) := r - \frac{e^{-\kappa t} y}{2}$$
 and $\sigma(t, x, y) := \sqrt{e^{-\kappa t} y}$.

 - Definition
 - Implied Volatility
- Quantization based Numerical Methodology
 - Quick reminder on Optimal Quantization (for d = 1)
 - For European Options pricing
 - For Bermudan and Barrier Options pricing
 - Discretization schemes
 - Product Recursive Quantization
 - Backward Step
- 3 Conclusion

First, the volatility

We build recursively the Markovian quantization tree $(\widehat{Y}_k)_{k \in [\![0,n]\!]}$ where $\widehat{Y}_{t_{k+1}}$ is the Voronoï quantization of \widehat{Y}_{k+1} defined by

$$\widetilde{Y}_{k+1} = \mathcal{M}^{\Delta}_{\widetilde{b},\widetilde{\sigma}} \big(t_k, \widehat{Y}_k, \widetilde{Z}_{k+1} \big), \qquad \widehat{Y}_{t_{k+1}} = \operatorname{Proj}_{\Gamma^{Y}_{N_2}} \left(\widetilde{Y}_{k+1} \right)$$

with $\Gamma_{N_2}^Y:=\{y_1^k,\ldots,y_{N_2}^k\}$ the optimal N_2 -quantizer of \widetilde{Y}_{k+1} and $\widetilde{Z}_{k+1}\sim \mathcal{N}(0,1)$.

Then, the log-asset

Now, using the fact that $(Y_t)_t$ has already been quantized and the Euler-Maruyama scheme of $(X_t)_t$, we define the Markov quantized scheme

$$\widetilde{X}_{k+1} = \mathcal{E}^{\Delta}_{b,\sigma} \big(t_k, \widehat{X}_k, \widehat{Y}_k, Z_{k+1} \big), \qquad \widehat{X}_{k+1} = \operatorname{Proj}_{\Gamma^X_{N_1}} \left(\widetilde{X}_{k+1} \right)$$

with $\Gamma_{N_1}^X := \{x_1^k, \dots, x_{N_1}^k\}$ the optimal N_1 -quantizer of \widetilde{X}_{k+1} and $Z_{k+1} \sim \mathcal{N}(0,1)$.

Bermudan Options

Its price, at time t_0 , is given by

$$V_0 := \sup_{\tau \in \{t_1, \cdots, t_n\}} \mathbb{E} \left[e^{-r\tau} \psi_{\tau}(X_{\tau}, Y_{\tau}) \mid \mathcal{F}_{t_0} \right].$$

Hence, we can define recursively the sequence of random variable L^p -integrable $(V_k)_{0\leqslant k\leqslant n}$:

$$\begin{cases} V_n = e^{-rt_n} \psi_n(X_n, Y_n), \\ V_k = \max \left(e^{-rt_k} \psi_k(X_k, Y_k), \mathbb{E}[V_{k+1} \mid \mathcal{F}_k] \right), \qquad 0 \leqslant k \leqslant n-1 \end{cases}$$

called Backward Dynamical Programming Principle.

Bermudan Options

Using the Product Recursive Quantizer

We approximate the *Backward Dynamical Programming Principle* by the following sequence involving the couple $(\hat{X}_k, \hat{Y}_k)_{0 \le k \le n}$:

$$\begin{cases} \hat{V}_n = e^{-rt_n} \, \psi_n(\hat{X}_n, \hat{Y}_n), \\ \hat{V}_k = \max \Big(e^{-rt_k} \, \psi_k(\hat{X}_k, \hat{Y}_k), \mathbb{E} \left[\hat{V}_{k+1} \mid (\hat{X}_k, \hat{Y}_k) \right] \Big), \qquad k = 1, \dots, n-1 \end{cases}$$

T. Montes

Bermudan Options

Using the Product Recursive Quantizer

The last equation can be rewritten

$$\begin{cases} \hat{v}_n(x_i^n, y_j^n) = \mathrm{e}^{-rt_n} \, \psi_n(x_i^n, y_j^n), & i = 1, \dots, N_1, \quad j = 1, \dots, N_2, \\ \hat{v}_k(x_i^k, y_j^n) = \max \left(\mathrm{e}^{-rt_k} \, \psi_k(x_i^k, y_j^n), \sum_{l=1}^{N_1} \sum_{m=1}^{N_2} \pi_{(i,j),(l,m)}^k \hat{v}_{k+1}(x_l^{k+1}, y_m^{k+1}) \right), \\ k = 1, \dots, n-1, \quad i = 1, \dots, N_1, \quad j = 1, \dots, N_2. \end{cases}$$

with $\pi_{(i,j),(l,m)}^k := \mathbb{P}(\widehat{X}_{k+1} = x_l^{k+1}, \widehat{Y}_{k+1} = y_m^{k+1} \mid \widehat{X}_k = x_i^k, \widehat{Y}_k = y_j^k)$. Finally, the approximation of the price of the bermudan option is given by

$$\mathbb{E}\left[\widehat{v}_k(x_0, \widehat{Y}_0)\right] = \sum_{i=1}^{N_{2,0}} p_i \widehat{v}_k(x_0, y_i^0)$$

with $p_i := \mathbb{P}(\hat{Y}_0 = y_i^0)$ previously defined.

Barrier Options

A Barrier option is a path-dependent financial product whose payoff at maturity date T depends on the value of the process X_T at date T and its maximum or minimum over the period [0, T]. More precisely, we are interested by options with the following types of payoff h

$$h = f(X_T) \, \mathbb{1}_{\{\sup_{t \in [\mathbf{0},T]} X_t \in I\}} \qquad \text{or} \qquad h = f(X_T) \, \mathbb{1}_{\{\inf_{t \in [\mathbf{0},T]} X_t \in I\}}$$

where I is an unbounded interval of \mathbb{R} , T is the maturity date and f can be any vanilla payoff function (Call, Put, Spread, Butterfly, ...).

Barrier Options

Using a representation formula

Now, using the representation formula based on the **conditional law of the Brownian Bridge** for the price of up-and-out options \bar{P}_{UO} and down-and-out options \bar{P}_{DO}

$$\bar{P}_{\textit{UO}} := \mathrm{e}^{-rT} \, \mathbb{E} \left[f(\bar{X}_{\textit{T}}) \, \mathbb{1}_{\sup_{t \in [\mathbf{0}, \, \mathit{T}]} \bar{X}_t \leqslant L} \right] = \mathrm{e}^{-rT} \, \mathbb{E} \left[f(\bar{X}_{\textit{T}}) \prod_{k=0}^{n-1} G_{(\overline{X}_k, \overline{Y}_k), \bar{X}_{k+1}}^k(L) \right]$$

where L is the barrier and

$$G_{(x,y),z}^k(u) = \left(1 - \mathrm{e}^{-2n\frac{(x-u)(z-u)}{T\sigma^2(t_k,x,y)}}\right) 1_{\{u \geqslant \max(x,z)\}}$$

Equivalent formulas for other standard Barrier options.

Barrier Options

Using the Product Recursive Quantizer

Finally, replacing (\bar{X}_k, \bar{Y}_k) by (\hat{X}_k, \hat{Y}_k) and using a recursive algorithm yield

$$\begin{cases} \hat{V}_n = e^{-rT} f(\hat{X}_n), \\ \hat{V}_k = \mathbb{E} \left[g_k(\hat{X}_k, \hat{Y}_k, \hat{X}_{k+1}) \hat{V}_{k+1} \mid (\hat{X}_k, \hat{Y}_k) \right], \qquad 0 \leqslant k \leqslant n-1 \end{cases}$$

that can be rewritten

$$\begin{cases} \hat{v}_{n}(x_{i}^{n}, y_{j}^{n}) = e^{-rT} f(x_{i}^{n}), & i = 1, \dots, N_{1}, \quad j = 1, \dots, N_{2} \\ \hat{v}_{k}(x_{i}^{k}, y_{j}^{n}) = \sum_{l=1}^{N_{1}} \sum_{m=1}^{N_{2}} \pi_{(i,j),(l,m)}^{k} \hat{v}_{k+1}(x_{l}^{k+1}, y_{m}^{k+1}) g_{k}(x_{i}^{k}, y_{j}^{k}, x_{l}^{k+1}), \\ k = 1, \dots, n-1, \quad i = 1, \dots, N_{1}, \quad j = 1, \dots, N_{2} \end{cases}$$

with
$$\pi_{(i,j),(l,m)}^k := \mathbb{P}(\widehat{X}_{k+1} = x_l^{k+1}, \widehat{Y}_{k+1} = y_m^{k+1} \mid \widehat{X}_k = x_i^k, \widehat{Y}_k = y_j^k)$$
 and $g_k(x,y,z) = G_{(x,y),z}^k(L)$.

T. Montes Optimal Quantization 29 / 31

Conclusion

So far

- Introduced a model with steeper smile volatility surface for short maturities than Standard Heston model.
- Fast numerical solution for the pricing of European, Bermudan and Barrier options.
